

ABSTRACT OF THE DISCLOSURE

In a method for generating an IPDS data stream, different levels are defined with level numbers, whereby in each level a group of print data is combined on which the same operation is implemented. The operations are defined by operation numbers. A linkage exists between the level numbers and the operation numbers such that an operation number can be unambiguously assigned to a level number so that it can be determined using the linkage which level is provided for which operation. It is not necessary to generate and to maintain complex tables in order to be able to administrate the level corresponding to the required specification.
